infrared spectroscopy is a new and innovative technology to study protein folding misfolding events in the broad arsenal of techniques conventionally used in this field the progress in understanding protein folding and misfolding is primarily due to the development of biophysical methods which permit to probe conformational changes with high kinetic and structural resolution the most commonly used approaches rely on rapid mixing methods to initiate the folding event via a sudden change in solvent conditions traditionally techniques such as fluorescence circular dichroism or visible absorption are applied to probe the process in contrast to these techniques infrared spectroscopy came into play only very recently and the progress made in this field up to date which now permits to probe folding events over the time scale from
