every graph has a line graph but not all graphs are line graphs of some graph certain types of induced subgraphs indicate whether a graph is a line graph for example the claw is not a line graph this thesis gives a careful characterization of the main theorem of line graphs that is the necessary and sufficient conditions for a graph to be a line graph we show the relationship between triangles forbidden subgraphs krausz partitions and line graphs by providing additional lemmas which aim to support the main theorem less attention has been devoted to line graphs of directed graphs de bruijn graphs give a motivation to investigate this class since they are directed line graphs another motivation for learning about directed line graphs arises from the study of the sum product algorithm for low density parity check codes we work with a very general class of directed graphs that allow multiple edges and loops which are called nets by harary we investigate the flow net and compare it to the line graph to lay the foundation for future study of directed line graphs

this volume contains the proceedings of the 1990 spring school of theoretical computer science devoted to the semantics of concurrency the papers are of two kinds surveys and tutorials introducing the subject to novices and students and giving updates of the state of the art research papers presenting recent achievements in the semantics of concurrency the contributions explicate the connections similarities and differences between various approaches to the semantics of concurrency such as pomsets and metric semantics event structures synchronization

trees fixpoints and languages traces ccs and petri nets and categorical models they also cover and compare the various notions of observation and bisimulation equivalences logics for concurrency and applications to distributed systems
